

Template Matching (TM) project

The goal of the project is to write a full TM pipeline

Inputs: 3D template in .pdb format and a micrograph in .mrc format

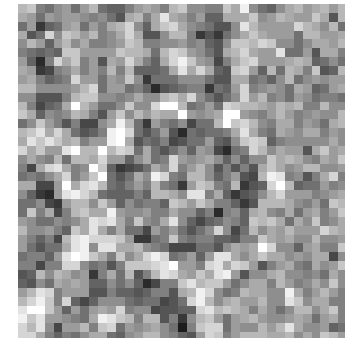

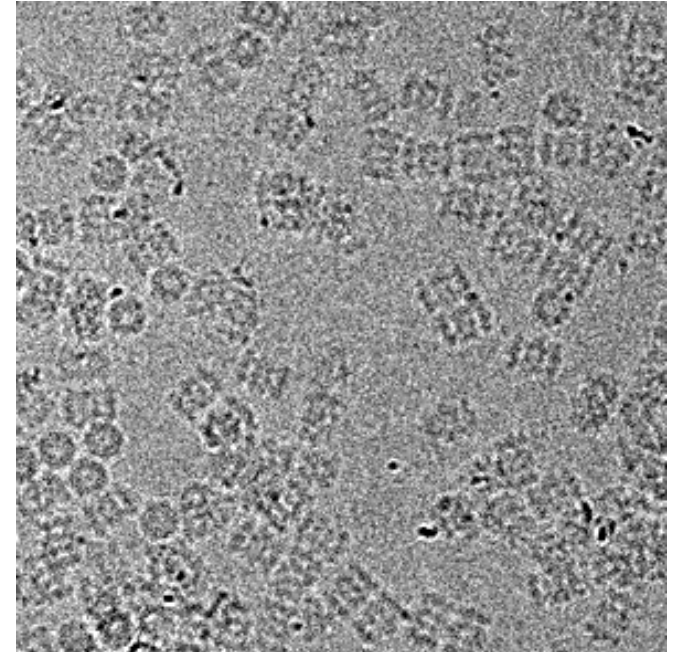

Output: extracted particles

Baseline: making the projection of the top view & identifying all (or most) top views in a micrograph

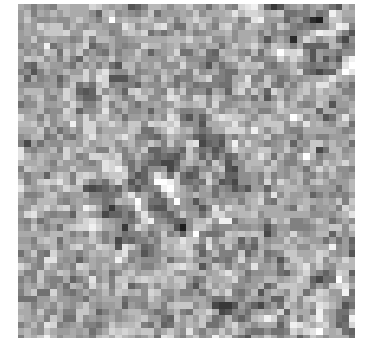

To go further: making a projection of the side view and & identifying both the top and the side views

(Tip: the template for the side view will have to be rotated & the rotation step optimized)

The project has to be progressively uploaded on github (the progress will be taken into account for the final grade, last minute uploading of the full project into an empty repository won't be penalized, but continuous progress will be rewarded)
